INDEPENDENT MARKET MONITORING

BITCOIN BOTTOM WATCH

Evidence-family chart report

Market observations through 2026-10-29 (UTC)

Generated 30 October 2026 07:42 UTC

ON-CHAIN VALUATION / CYCLE STRUCTURE / DEMAND & LIQUIDITY / PRICE MOMENTUM / SENTIMENT

Research note: Indicator confirmation is not a prediction or a trading authorization. Missing independent data reduces confidence in bottom and early-bull inferences.

Executive evidence summary

This assessment differentiates evidence supporting a completed cycle bottom from evidence supporting an emerging sustained bull market. Technical momentum is ONE evidence family, not multiple independent confirmations.

Evidence family	Bottom / early-bull interpretation
On-chain valuation	Verified recent holder positioning; delayed MVRV/realized-price history as context
Cycle structure	Pi Cycle Bottom: no new crossover; absent signal does not rule out bottom
Demand / liquidity	Dated Bitcoin ETF holdings history; current net USD ETF flows unverified
Price / momentum	Confirmed monthly RSI bullish crossover; EMA ribbon not fully ordered
Sentiment	30 / Fear (overlay only)

Observed BTC/USD daily close: **US$77,792.67** on **2026-10-29**. Last completed week: 2026-10-25; last completed month: 2026-09-30.

Overall assessment: Price/momentum evidence is constructive, but on-chain valuation and sustained demand cannot be assessed with sufficient confidence. Neither a definitive completed bottom nor an early bull market is independently confirmed by this report.

Tranche discipline: No additional borrowed-funds tranche is justified by technical indicators alone. Bottom/bull probabilities are not quantified without an adequate independent evidence base.

Data: 30 October 2026 07:42 UTC. Source: Bitstamp daily OHLC published and validated by GitHub collector.

Family 1 | On-chain valuation

STATUS: NOT VERIFIED - on-chain data feed did not pass validation

MVRV, realized price, realized profit/loss and long-term-holder activity require reliable synchronized observations. No substitute numerical charts have been published.

How to read it

Realized price is the aggregate on-chain last-moved cost basis. MVRV compares market cap to realized cap. Low or rising-from-low valuations can support bottom formation, but must be interpreted with independent demand and holder behaviour.

Bottom or early-bull assessment

INCONCLUSIVE. Without verified on-chain observations, technical momentum cannot establish undervaluation or long-term-holder accumulation.

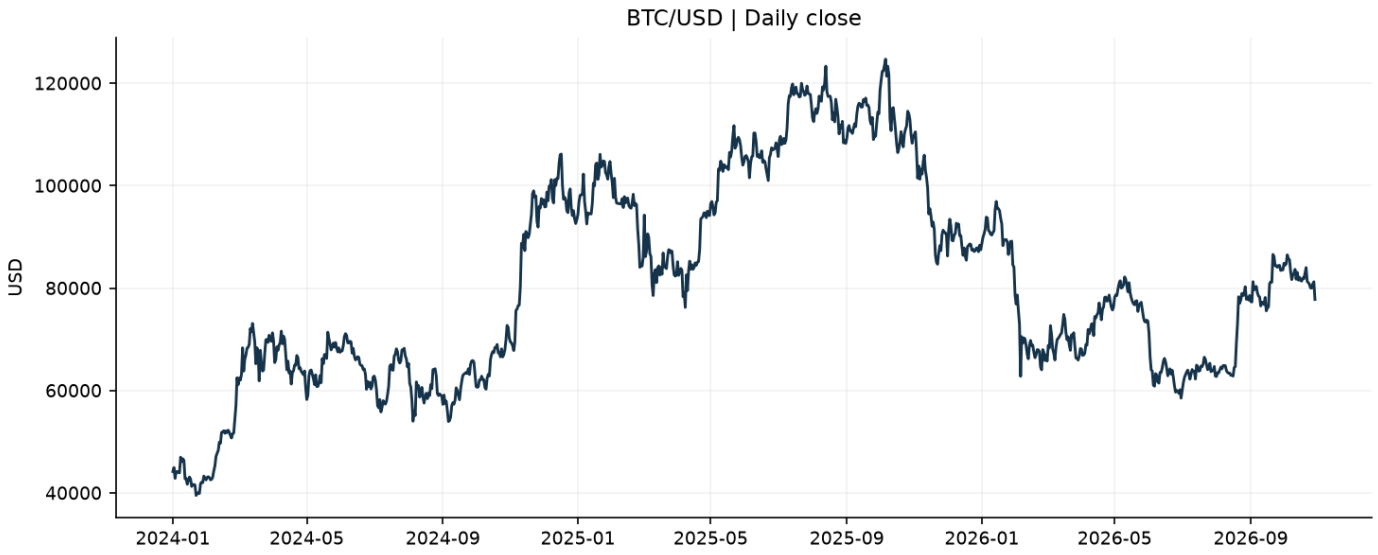

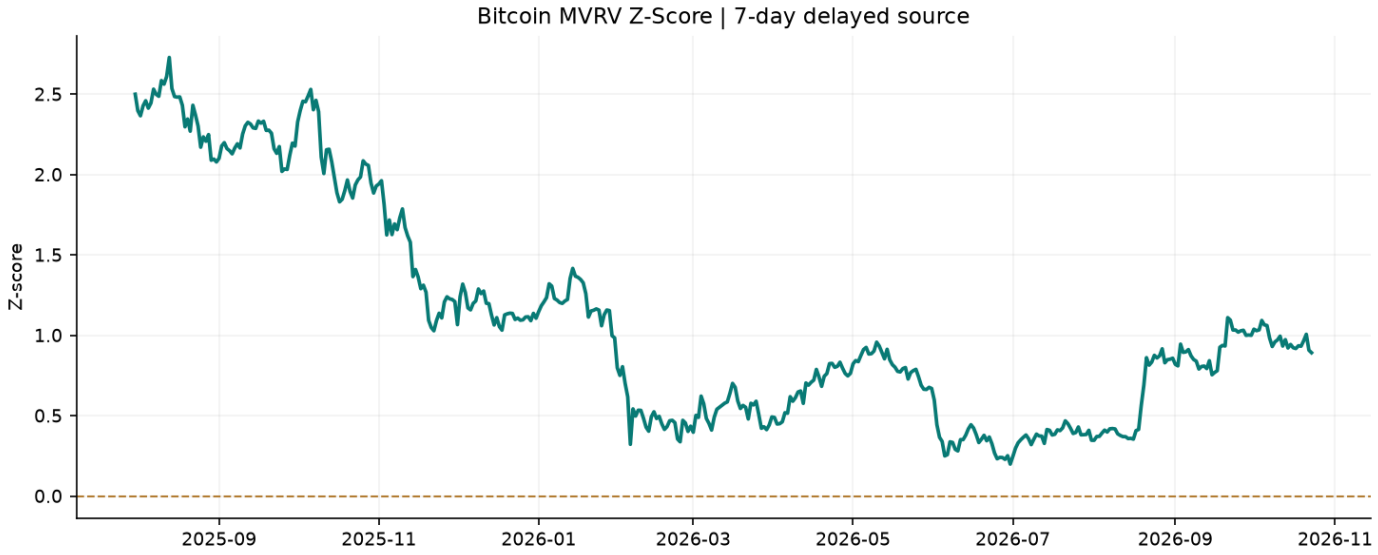

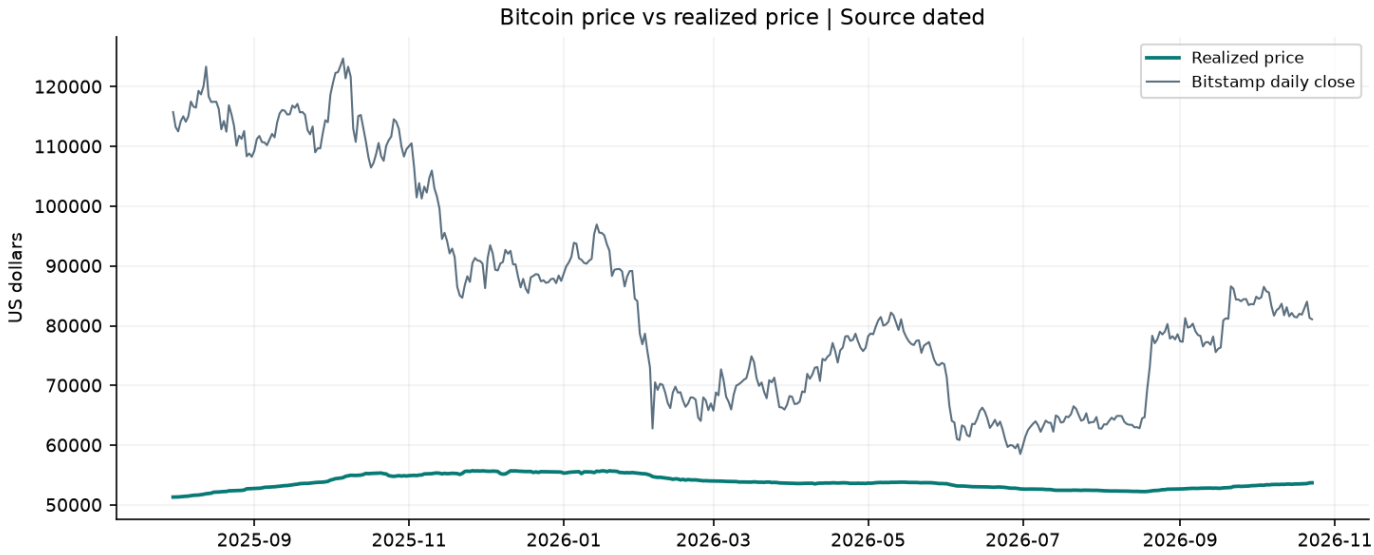

Chart shows market price ONLY (Bitstamp standard candles), not on-chain valuation.

How to read MVRV Z-Score

Low or negative values can accompany historically depressed valuations; rising values from those lows can support recovery. This BGeometrics FREE observation is delayed by 7 days. It is historical context, NOT a synchronized present-day reading.

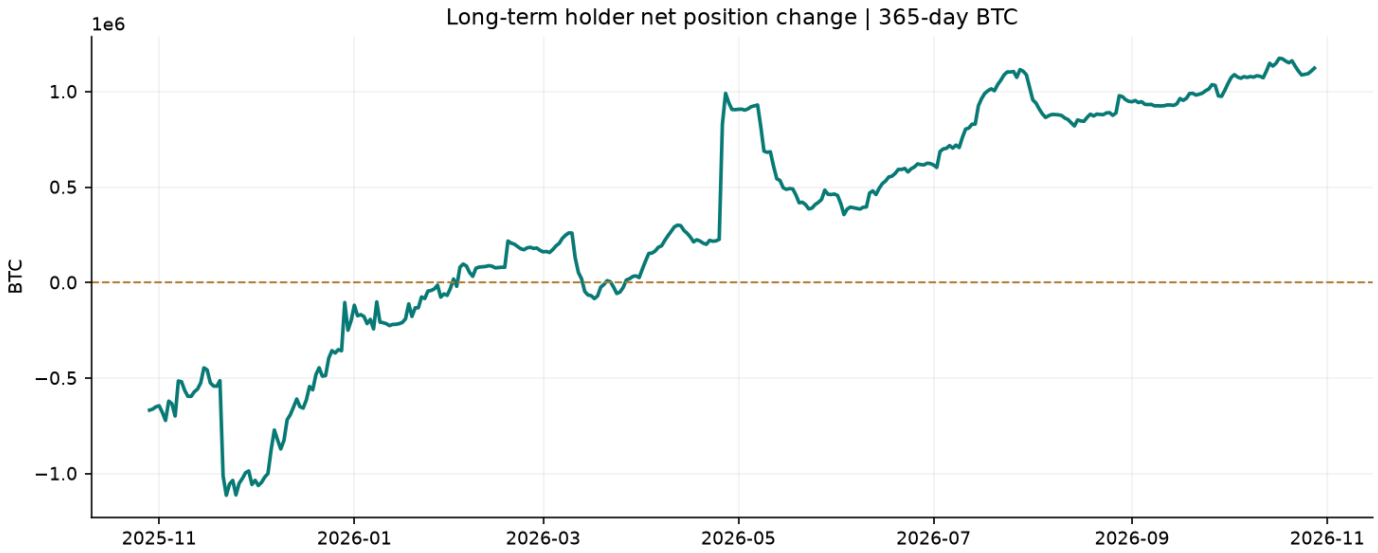

Delayed MVRV Z-Score (2026-10-23): **0.892**. A positive value is not itself proof of a bottom or bull regime.

How to read realized price

Compare the verified BTC market price on each common calendar date with aggregate holder cost basis. Approaching or falling below the realized price has historically signaled more depressed valuation, but not guaranteed reversals. The realized price is delayed by 7 days.

Delayed realized price (2026-10-23): **US$ 53,704**; do not compare it to an undated or current spot price as a synchronous observation.

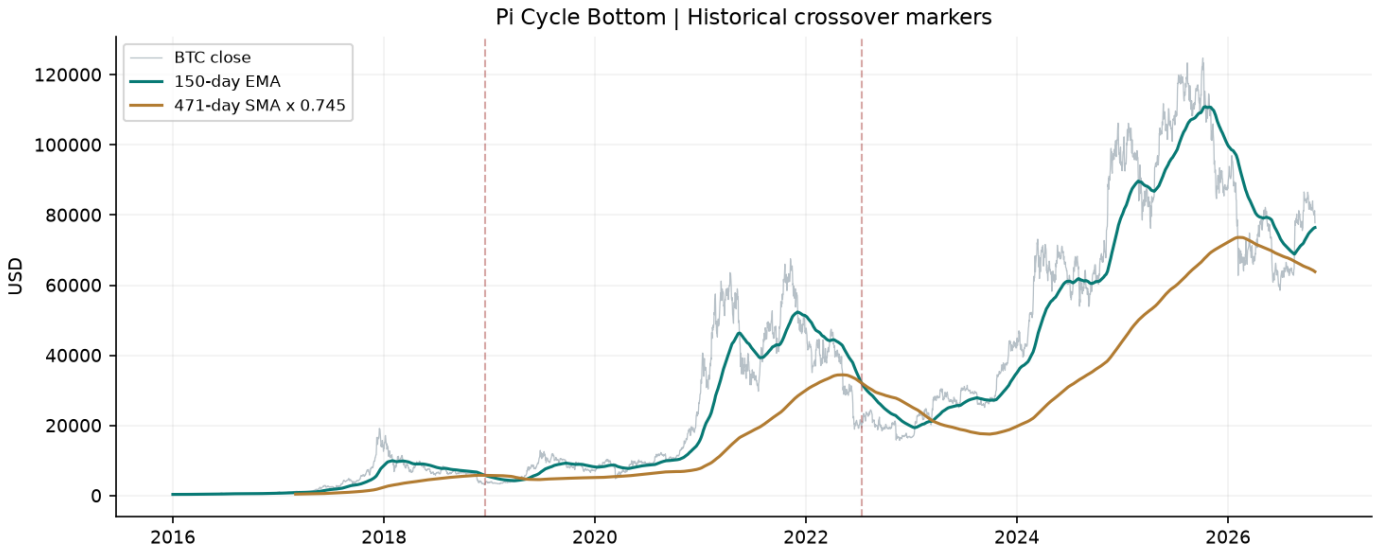

How to read long-term holder positioning

Positive 365-day net position change indicates holders classified long term cumulatively added to their balance over a year. Negative readings mean net distribution. It is a slow cycle signal, not an intraday bottom trigger. Confirm methodology, changes in classification and price action before relying on it.

Long-term-holder 365-day net position change (2026-10-28): **1,122,610 BTC**. Positive indicates net accumulation over this lookback, supportive of structural holding, not alone proof of a new bull.

Historical on-chain source: BGeometrics public daily API. Valuation metrics are explicitly delayed on its free tier. No missing/stale reading is counted as fresh tranche confirmation.

Family 2 | Cycle / structural

How to read this chart

The green curve is the 150-day EMA, and gold is 0.745 x the 471-day SMA. A Pi Cycle Bottom event is recorded only when the adjusted long average crosses ABOVE the shorter EMA. Dashed markers show historical occurrences; they are not forward predictions.

Latest verified values (2026-10-29): 150-day EMA **US$76,447**; adjusted 471-day SMA **US$63,856**. New bottom crossover: **NO**.

Bottom or early-bull assessment

No new Pi Bottom crossover. This does not deny a completed bottom: the indicator is episodic, can lag, and may not trigger during every constructive market regime. It offers no fresh bottom confirmation today.

Source: Bitstamp standard BTCUSD daily closes, 150-day EMA and 471-day SMA x 0.745; historical dates and latest values validated to published JSON.

Family 3 | Demand / liquidity

STATUS: ETF FLOW SERIES UNAVAILABLE / UNVERIFIED

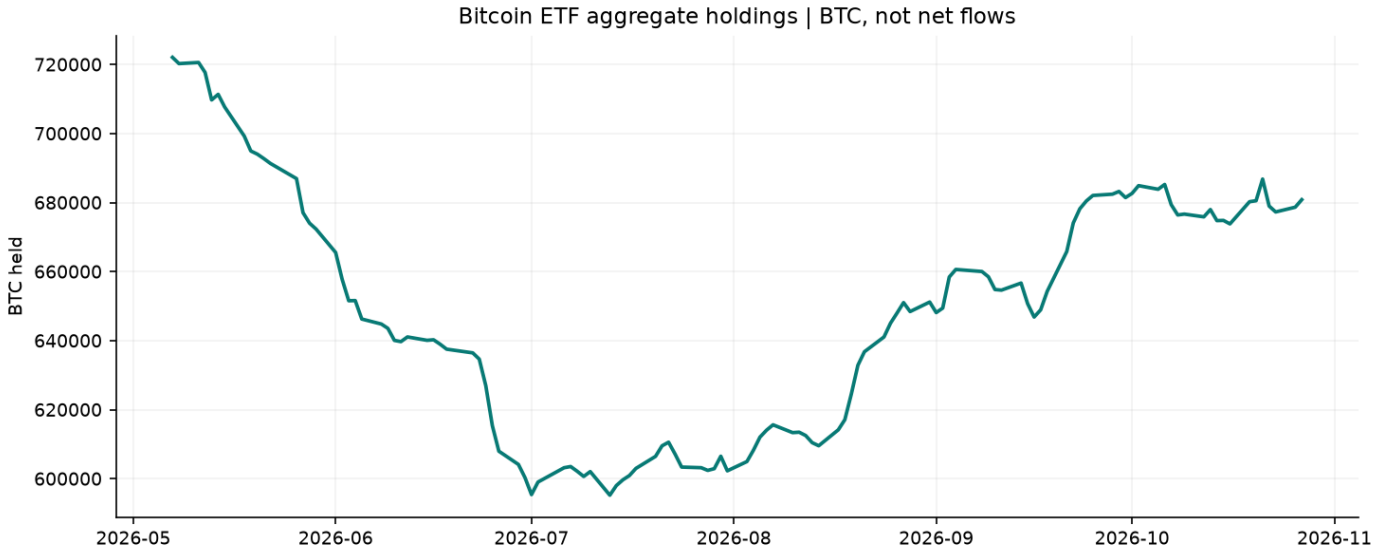

How to read ETF flows

Persistent net inflows across multiple sessions can support new capital demand; persistent outflows contradict the early bull case. Separate ETF flows from derivatives short covering and total spot market demand.

Bottom or early-bull assessment

INCONCLUSIVE. No validated fresh ETF flow series was available; no substitute graph has been fabricated.

Primary source: https://farside.co.uk/bitcoin-etf-flow-all-data/ .

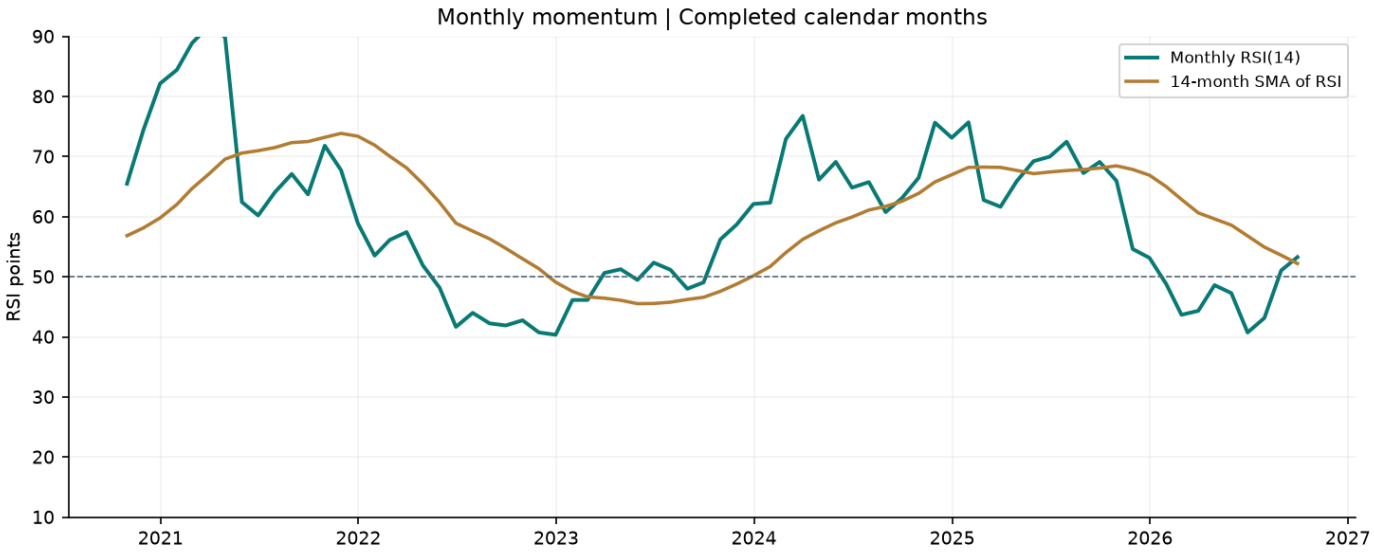

How to read ETF Bitcoin holdings

This chart is the total BTC held in the provider ETF series, NOT daily USD ETF net inflows. A persistent rise can be consistent with net creation/accumulation; a fall can be consistent with redemptions. Changes can also reflect reporting/reconciliation. It does not replace independently verified Farside flows.

Latest ETF holdings observation (2026-10-27): **680,870 BTC**. Delayed aggregate holdings can provide demand context, but cannot by itself establish current fresh-capital demand.

Source: BGeometrics /v1/etf-btc-total. Separate from daily USD net flows, which remain unverified when Farside is inaccessible.

Family 4 | Price and momentum

How to read monthly RSI

The teal line is 14-period Wilder RSI on monthly BTC closing prices; gold is the 14-month simple average of RSI. A confirmed monthly bullish crossover requires the completed RSI bar to close above the RSI average after previously being at or below it. A crossover supports momentum recovery, not necessarily deep valuation.

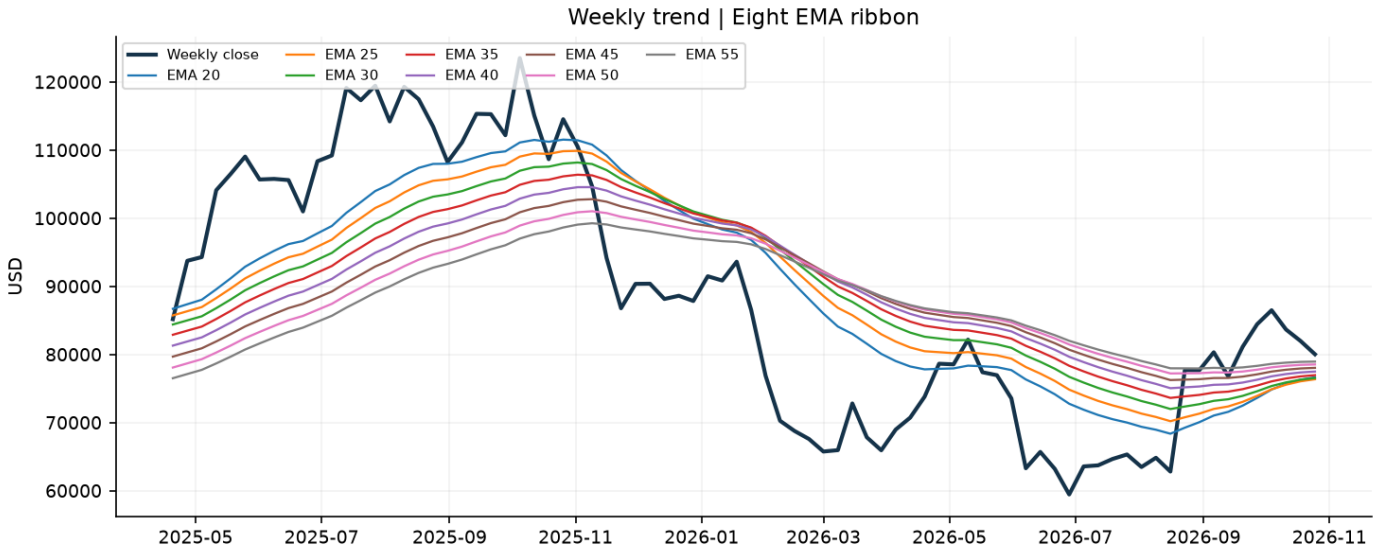

Completed month 2026-09-30: RSI **53.27** vs RSI-SMA **52.21**; bullish crossover: **YES**.

Bottom or early-bull assessment

Momentum recovery is supported by a completed monthly RSI crossover. This improves the technical case for an early bull, but cannot independently confirm the cycle bottom.

Source: Bitstamp standard daily closes, completed UTC months only; latest output cross-checked to GitHub collector.

Family 4 | Weekly trend confirmation

How to read the EMA ribbon

A strictly bullish ordering requires EMA20 > EMA25 > EMA30 > EMA35 > EMA40 > EMA45 > EMA50 > EMA55. BTC closing above every EMA is constructive but insufficient for a fully ordered bullish ribbon. Watch slope, persistence and widening separation.

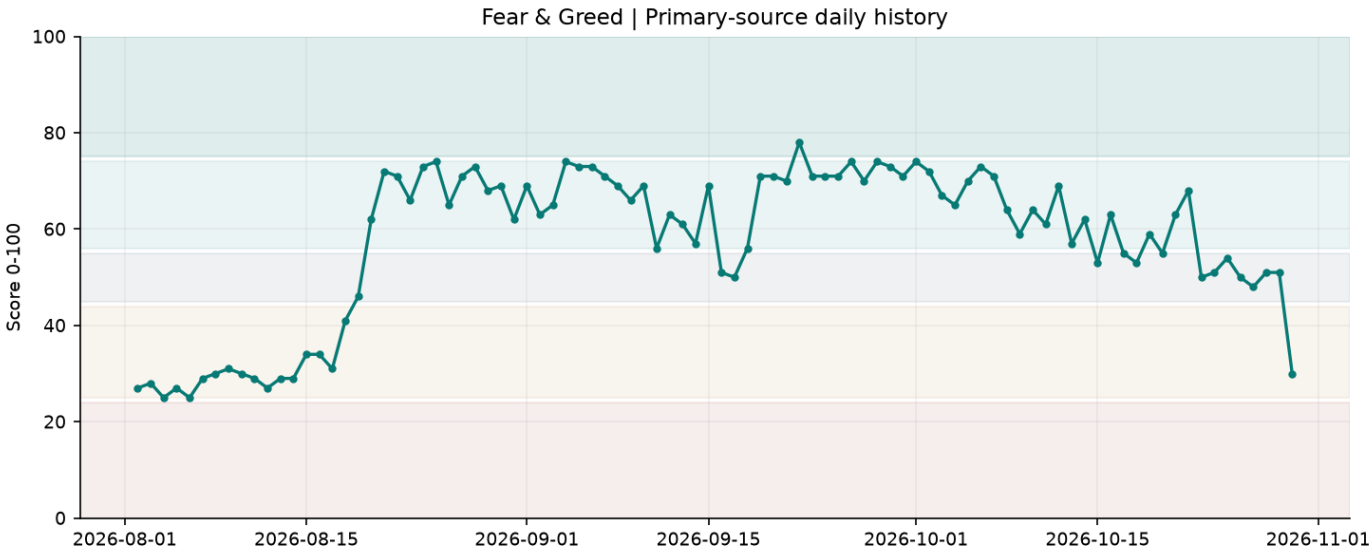

Last completed weekly close (2026-10-25): **US$80,048.21**. Above all eight averages: **YES**. Fully bullish ordering: **NO**.

Bottom or early-bull assessment

Price above the weekly EMA ribbon supports improving trend, but incomplete EMA ordering means the stronger structural confirmation has not yet arrived. Treat this together with monthly RSI as ONE momentum family.

Source: Bitstamp standard BTCUSD daily prices aggregated into fully completed UTC Sunday-ending weeks.

Sentiment overlay | Fear & Greed

Latest verified value: **30/100 (Fear)**, 2026-10-30. Source: Alternative.me primary API.

How to read it

Shaded bands correspond to extreme fear (0–24), fear (25–44), neutral (45–55), greed (56–74) and extreme greed (75–100). Look for multiweek shifts; no single sentiment reading identifies a durable bottom.

Bottom or early-bull assessment

Contrarian fear can improve prospective entry context but is not independent proof of a bottom.

Source: https://api.alternative.me/fng/?limit=35&format;=json | VERIFIED (Alternative.me primary API, independently collected)

Sources and indicator integrity

All technical time series use verified daily Bitstamp BTC/USD standard closes, not Heikin Ashi. The daily series is checked for continuity and the month/week series contain only completed bars.

Published reference: https://raw.githubusercontent.com/tvella23/B-Bottom-Watch/main/latest.json

Pi Cycle: EMA(150, daily close) versus 0.745 x SMA(471, daily close); bullish crossover of the long adjusted SMA above the short EMA is the bottom event. RSI: Wilder(14) on completed monthly closes, compared with a simple moving average over 14 RSI observations. EMA ribbon: 20/25/30/35/40/45/50/55 on completed Sunday-ending weekly closes.

The report does not silently replace missing on-chain, ETF, stablecoin or derivatives statistics with stale web previews, a different data provider or illustrative numbers. Only dated, valid primary-source observations are plotted.

Future changes to calculated indicator methodology, source and aggregation rules require a revalidation against trusted chart references before publication.
